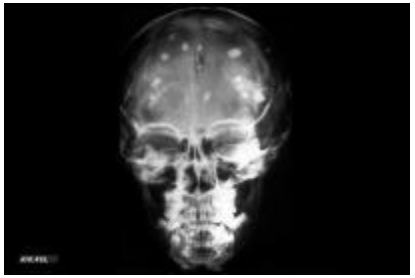
# Toxoplasmose congénitale :

# diagnostic et prise en charge

# Introduction



- **toxoplasmose congénitale**

- **importance clinique (France *en l'état actuel de la prise en charge*: 0,5/1000 naissances). 200 à 300 cas/ans sur 6 ans.**

- **épidémiologie (séroprévalence : variable 40 % en France)**

- **diagnostic biologique (séroconversion, diagnostic *in utero*, post natal)**

- **prise en charge selon protocole.**

# Séroconversion - infection maternelle

**Pourquoi ?**

**Objectifs : traiter, prévenir les lésions fœtales**

**Efficacité (Wallon *et al* CID 2013, Garweg *et al* Pathogens 2022)**

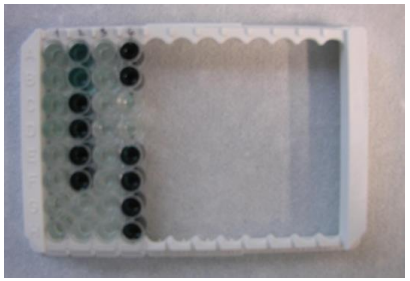
**Cadre légal : différent selon pays (France, Autriche, Suisse +/- …)**

**Dépistage (après la prévention)**

# Séroconversion - infection maternelle

- Dye test

- Blot II



- I.F.I. (Immunofluorescence indirecte)
- Elisa
  - les plus utilisées
  - très nombreuses trousses
  - antigènes, révélations, etc…
  - performances variables selon trousses
- ISAgA
  - précocité
  - sensibilité
  - non automatisée

# Séroconversion - infection maternelle

**Avidité des IgG**

- **évolution de l'Elisa**
- **principe de l'affinité/avidité des anticorps**
- **exclusion d'une infection récente**
- **peu de trousses commerciales disponibles**

# Séroconversion - infection maternelle

## Cinétiques

**cinétiques + avidité**

**= datation de la séroconversion**

# Detection of Anti-*Toxoplasma* Immunoglobulin M in Pregnant Women

Liesenfeld et al. (1) recently published a very interesting article on an old but still often embarrassing problem, the detection of anti-*Toxoplasma* immunoglobulin M (IgM) in pregnant women. We completely agree with their conclusions, but we would like to add some more comments.

First, the evaluation of IgM detection with a serology kit is easy when the follow-up of patients allows the collection of consecutive sera which definitely confirm either a seroconversion (with the first serum sample being negative) or a persisting negative serology. However, in routine laboratories, biologists are most often faced with the problem of a first serum sample with IgG and IgM, or IgM alone in a pregnant woman without any previous result. The biologist has to give a first reply to the physician, the definitive conclusion coming from the study of a second serum sample 3 weeks afterward, in countries (such as France) where this is routinely done. Thus it is of great importance for the clinical microbiologist to know perfectly well the performance of the kit he or she uses. This can be ascertained only by carrying out comparative studies with previously described tests, even if none of the techniques is the absolute reference since there is no real "gold standard" for IgM detection, as specified by Liesenfeld et al. (1, 2). A World Health Organization reference serum exists for IgG, but not for IgM (3). That is why the words "sensitivity" and "specificity" must be carefully interpreted in these studies. They are not absolute but are related to the reference technique (which again is not a gold standard) used specifically in each study and clearly defined as such. The real medical sensitivity (together with the earliness of detection) and specificity for the diagnosis of acquired toxoplasmosis can be evaluated only with true seroconversions and consecutive negative sera, respectively.

Second, it is true that the information given to a pregnant woman that she has a positive result in an IgM test for *Toxoplasma* can lead to exaggerated distress, even if successive controls can be performed. We would like to insist on the fact that it is the responsibility of both the physician and the biologist to carefully interpret the results and to discuss together the content of the message to be delivered to the patient. Since no IgM detection kit is absolutely perfect, the clinical microbiologist in a routine laboratory must give not only a reply concerning the test results but also, from a medical point of view, an interpretation concerning the possibility, or not, of infection acquired after the beginning of pregnancy. If this is impossible, he or she should refer the sample to a reference laboratory, which can give more precise information, mainly by comparing the results obtained by different serological methods with different target antigens and antibodies with different kinetics.

This is the only way, to date, to avoid the tragedies that could be induced by false-positive results and/or results indicating persistent (remaining after infection acquired in the distant past) IgM specific for *Toxoplasma gondii*.

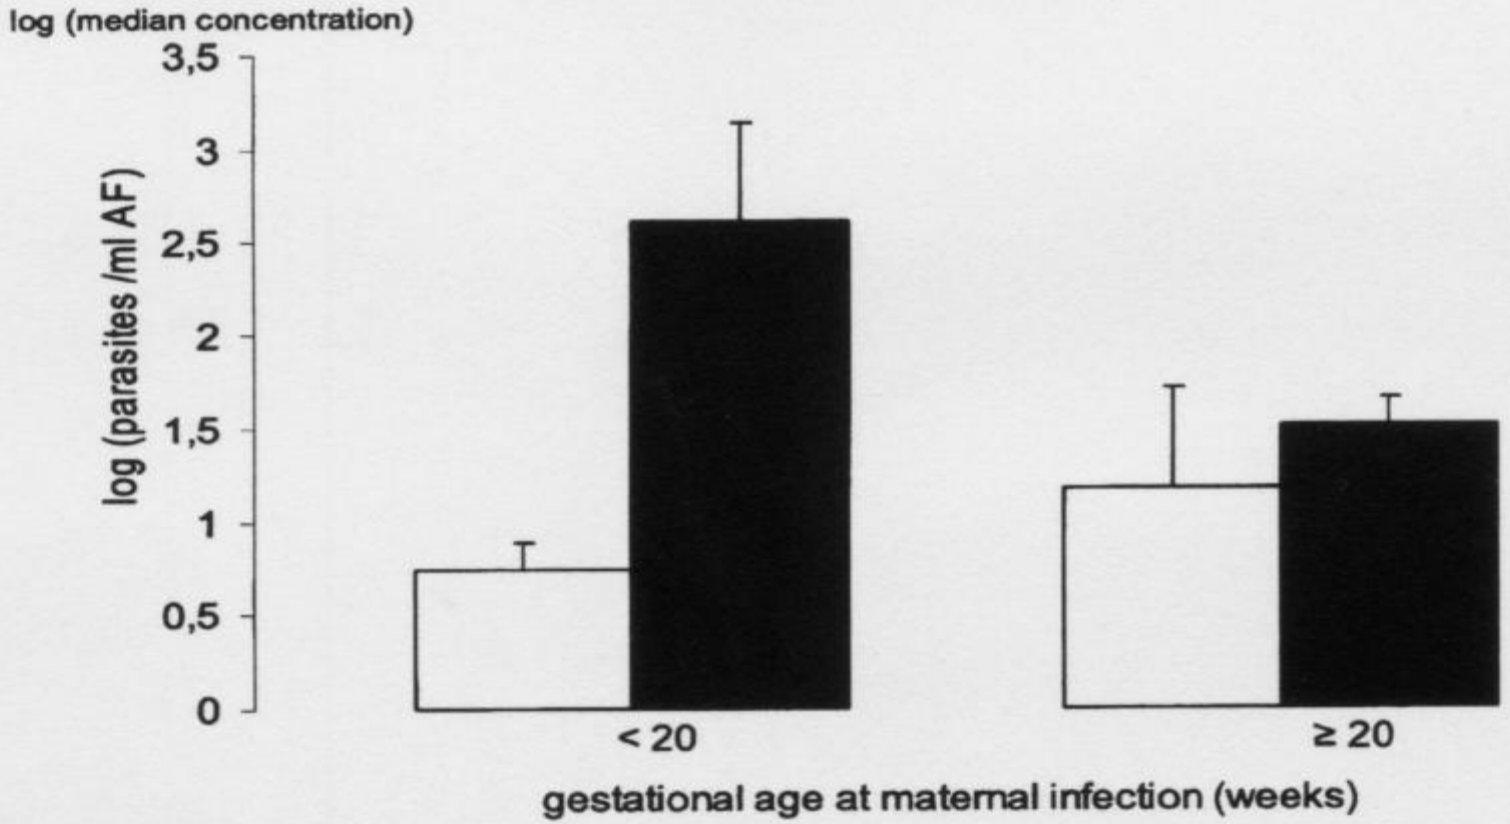

**Figure 2** Comparison of median (interquartile range) parasite concentrations in AF between cases with subclinical infection (*unshaded bars*) and cases with infectious sequelae (*shaded bars*) for maternal infections acquired before or after 20 weeks' gestation. Clinical status was recorded either at birth or after fetal death (fetopathologic examination).

# Diagnostic *in utero*

**Valeur du diagnostic *in utero***

- **sensibilité/spécificité de la PCR (qualitative et quantitative)**
- **apport de la quantification ?**

# Diagnostic *in utero*

**Toutes techniques et prélèvements confondus**

**- sensibilité du diagnostic anténatal entre 90 et 100 %**

**- spécificité 100 %**

# Diagnostic néonatal et postnatal

**Pourquoi ? Indications**

- **enfant né d'une mère ayant présenté une infection toxoplasmique pendant la grossesse**
- **diagnostic *in utero* ou non**
- **traitement ?**
- **« gold standard » : sérologie à un an**

# Diagnostic néonatal et postnatal

## Placenta

- intéressant si absence de diagnostic ante-natal (Robert-Gangneux *et al*, *Trends Parasitol.* 2011)

- souris, PCR

- sensibilité, spécificité

# Suivi du nouveau né et de l'enfant

**Sérologies « classiques »**

- **IgG, IgM, IgA**
- **IFI, ELISA, ISAgA**
- **cinétique**
- **persistance ou disparition des IgG**

# Suivi du nouveau né et de l'enfant

## Western Blot

- profils comparés mère/enfant

-permet de mettre en évidence les anticorps néo-synthétisés par le nouveau-né

# Suivi du nouveau né et de l'enfant

## Protocole de suivi

naissance (J +5), 1 mois, puis tous les 2 mois jusqu'à 6 mois

puis suivi sérologique jusqu'à un an, sauf si négativation des IgG

***Background.*** The biological diagnosis of toxoplasmosis after allogeneic hematopoietic stem cell transplantation (HSCT) is based on the detection of *Toxoplasma gondii* DNA in blood specimens or other samples. Serological testing is used mainly to define the immunity status of the patient before HSCT. The aim of our study was to examine the performance of polymerase chain reaction (PCR) and serological techniques in the diagnosis of toxoplasmosis after HSCT.

***Methods.*** Seventy patients underwent allogeneic HSCT from September 2004 through September 2006. DNA was detected by PCR, and immunoglobulin G and immunoglobulin M were detected by enzyme-linked immunosorbent assay.

***Results.*** The results of immunoglobulin G detection before allogeneic HSCT were positive in 40 (57.1%) of the patients and negative in 30 (42.9%). After HSCT, 57 patients (81.4%) had test results that were negative for immunoglobulin M and had negative results of DNA detection, without toxoplasmosis infection. Four patients (5.7%) had at least 4 samples with positive PCR results and/or test results positive for immunoglobulin M against *T. gondii;* toxoplasmosis was then confirmed by clinical symptoms. Nine patients (12.9%) with positive PCR results and 1 or 2 samples with test results negative for immunoglobulin M were considered to have asymptomatic *T. gondii* infection. Reactivation of latent infection was the cause of toxoplasmosis in 3 of the 4 patients, and toxoplasmosis occurred as a primary infection in 1 patient. The detection of specific anti–*T. gondii* immunoglobulin M was the only biological evidence of toxoplasmosis in 2 patients, and samples were positive for immunoglobulin M before PCR was performed in 1 patient.

***Conclusions.*** Thus, after HSCT, all patients were at risk for toxoplasmosis; all patients who receive HSCTs should be followed up with biological testing that combines PCR and serological techniques.

Transplantation activity is increasing, leading to a growing number of patients at risk for toxoplasmosis. We reviewed toxoplasmosis prevention practices, prevalence, and outcomes for hematopoietic stem cell transplant (HSCT) and solid organ transplant (SOT; heart, kidney, or liver) patients in Europe. We collected electronic data on the transplant population and prevention guidelines/regulations and clinical data on toxoplasmosis cases diagnosed during 2010–2014. Serologic pretransplant screening of allo-hematopoietic stem cell donors was performed in 80% of countries, screening of organ donors in 100%. SOT recipients were systematically screened in 6 countries. Targeted anti-*Toxoplasma* chemoprophylaxis was heterogeneous. A total of 87 toxoplasmosis cases were recorded (58 allo-HSCTs, 29 SOTs). The 6-month survival rate was lower among *Toxoplasma*-seropositive recipients and among allo-hematopoietic stem cell and liver recipients. Chemoprophylaxis improved outcomes for SOT recipients. Toxoplasmosis remains associated with high mortality rates among transplant recipients. Guidelines are urgently needed to standardize prophylactic regimens and optimize patient management.

**ABSTRACT**

**Introduction**. Toxoplasmosis is a life-threatening parasitic disease for hematopoietic stem cell transplant (HSCT) and solid organ transplant (SOT) recipients. The risk of toxoplasmosis in transplant patients mainly depends on the degree of immunosuppression, the tropism of *Toxoplasma gondii* for the grafted tissue, and the seroprevalence in the general population. Although transplant recipients with toxoplasmosis have a high mortality rate, there are neither well-defined recommendations nor a consensus for the management of this disease in these patients.

**Areas covered**. This review focuses on the management of toxoplasmosis in transplant recipients and discusses the various strategies for diagnosis, prevention, treatment, and follow-up in clinical practice. The literature search was conducted on publications in English and French using the search terms '*Toxoplasma gondii*,' 'organ transplant,' and 'transplant recipients.'

**Expert commentary**. The diagnosis of toxoplasmosis has greatly improved over the last two decades, but it is still a fatal illness. Non-specificity of the symptoms, resulting in a delay before diagnosis, and therapeutic failure are the main causes of death. The development of active treatments against cysts is one of the current challenges that will considerably improve the management of toxoplasmosis in transplant recipients by clearing chronic infection to avoid *T. gondii* reactivation.
